Folder Name Folder Description Abstract The hydroponic fish culture of tilapia (*Oreochromis mossambicus*) in the raceway pond system is investigated. This study examines the growth of tilapia in a fish rearing system. The results of a preliminary study on the effect of chlorophyll on tilapia showed that tilapia grew well under a light condition of 2000 lux and that the growth of tilapia was retarded under a light condition of 6000 lux. Therefore, the fish rearing system was designed as a raceway pond in order to reduce the light intensity. Also, a flow of water was designed in order to regulate the water depth. Under the fish rearing system, however, the fish grew normally. The fish culture in the raceway pond system was found to be beneficial in terms of the efficient use of water and the production of the tilapia fillets.Q: Why is it common to check for null but not for a null value? Consider this code: public void execute(MyObject object) { if (object!= null) { // do something } } Why would I want to test if a object is null (i.e. there is no value), but not if it is empty (i.e. the object has no properties or fields)? A: Here are a few points to clarify: Why would I want to test if a object is null (i.e. there is no value), but not if it is empty (i.e. the object has no properties or fields)? While your objection is very valid, I think you're misusing the word empty. In many cases, when you're checking for null, you're actually checking if the object has at least one property or field. And what you're really checking for, in some cases, is that the object has some value, even if that value is an empty string 2d92ce491b
