download. Counter-Strike  
download for  
PC/Windows. Continuous  
harvesting of algal biomass is a  
process where non-  
photosynthetic algae are  
harvested in an aqueous  
environment to remove  
contaminants from water, or to

---

provide organic material for animal or human consumption. A long-standing problem in the algal biomass harvesting process is the loss of light to the environment. In a typical algal biomass harvesting process, 20-80% of the energy is lost due to light reflection from the algal biomass and the darkening of the harvested algae due to the harvesting process. In the algal biomass harvesting process, the algae in the aqueous

---

environment is continually harvested. The harvesting process creates a dense algae mat in the water column. When the algae are harvested, the harvesting process creates a space that is devoid of algae. When the water with a dense algae mat flows through the process, the sunlight reflected by the algae biomass is lost. The algae biomass has a high light reflection factor of ~70% and when the algae is harvested, the

---

harvesting process creates a space that is devoid of algae, such that the light reflection factor decreases to zero. The loss of light creates a detrimental effect on the growth of algae in the subsequent harvesting process. This loss of light is particularly problematic in the harvesting of species that are native to freshwater environments. One such species is *Chlorella pyrenoidosa*, which
